## GLUCAGON RECEPTOR MODULATORS

## FIELD OF THE INVENTION

The present invention relates to compounds that are antagonists, mixed agonists/antagonists, partial agonists, negative allosteric modulators or inverse agonists of the glucagon receptor, pharmaceutical compositions comprising the compounds, and the uses of the compounds or compositions.

## BACKGROUND

Diabetes is a major public health concern because of its increasing prevalence and associated health risks. The disease is characterized by metabolic defects in the production and utilization of carbohydrates which result in the failure to maintain appropriate blood glucose levels. Two major forms of diabetes are recognized. Type I diabetes, or insulin-dependent diabetes mellitus (IDDM1 DM), is the result of an absolute deficiency of insulin. Type II diabetes, or non-insulin dependent diabetes mellitus (NIDDM2DM), often occurs with normal, or even elevated levels of insulin and appears to be the result of the inability of tissues and cells to respond appropriately to insulin. Aggressive control of NIDDM T2DM with medication is essential; otherwise it can progress into  $\beta$ -cell failure and insulin dependence.

Glucagon is a twenty nine amino acid peptide which is secreted from the  $\alpha$  cells of the pancreas into the hepatic portal vein thereby exposing the liver to higher levels of this hormone than non-hepatic tissues. Plasma glucagon levels decrease in response to hyperglycemia, hyperinsulinemia, elevated plasma non-esterified fatty acid levels and somatostatin whereas glucagon secretion is increased in response to hypoglycemia and elevated plasma amino acid levels. Glucagon, through activation of its receptor, is a potent activator of hepatic glucose production by activating glycogenolysis and gluconeogenesis.

The glucagon receptor is a 62 kDa protein that is activated by glucagon and is a member of the class B G-protein coupled family of receptors. Other closely related G-protein coupled receptors include glucagon-like peptide-1 receptor (GLP-1), glucagon-like peptide-2 receptor (GLP-2) and gastric inhibitory polypeptide receptor. The glucagon receptor is encoded by the GCGR gene in humans and these receptors are mainly expressed in the liver with lesser amounts found in the kidney, heart, adipose tissue, spleen, thymus, adrenal glands, pancreas, cerebral cortex and gastrointestinal tract. Stimulation of the glucagon receptor results in activation of adenylate cyclase and increased levels of intracellular cAMP.

Reports have indicated that an uncommon missense mutation in the GCGR gene is correlated with diabetes mellitus type 2 and one reported inactivating mutation of the glucagon receptor in humans causes resistance to glucagon and is associated with pancreatic  $\alpha$ -cell hyperplasia, nesidioblastosis, hyperglucagonemia and pancreatic neuroendocrine tumors. In rodent studies with GCGR knockout mice and mice treated with GCGR antisense oligonucleotides the mice exhibited improved fasting glucose, glucose tolerance and pancreatic  $\beta$ -cell function. In both healthy control animals and animal models of type 1 and type 2 diabetes, removal of circulating glucagon with selective and specific antibodies has resulted in a reduction of the glycemic level. More specifically, treatment of both mice and cynomolgus monkeys with GCGR-antagonizing antibodies (mAb B and mAb Ac) has been shown to improve glycemic control

without causing hypoglycemia. Recent mice studies have further shown that antagonism of the glucagon receptor results in improved glucose homeostasis through a mechanism which requires a functional GLP-1 receptor. Antagonism of the glucagon receptor resulted in compensatory overproduction of GLP-1, likely from the pancreatic  $\alpha$ -cells, and this may play an important role in intraislet regulation and maintenance of  $\beta$ -cell function.

A promising area of diabetes research involves the use of small molecule antagonists, mixed agonists/antagonists, partial agonists, negative allosteric modulators or inverse agonists of the glucagon receptor to lower the level of circulating glucagon and thereby lower the glycemic level. Therapeutically, it is anticipated that inactivation of the glucagon receptor would be an effective strategy for lowering blood glucose by reducing hepatic glucose output and normalizing glucose stimulated insulin secretion. Consequently, a glucagon antagonist, mixed agonist/antagonist, partial agonist, negative allosteric modulator or inverse agonist may provide therapeutic treatment for NIDDM T2DM and associated complications, inter alia, hyperglycemia, dyslipidemia, insulin resistance syndrome, hyperinsulinemia, hypertension, and obesity.

Several drugs in five major categories, each acting by different mechanisms, are available for treating hyperglycemia and subsequently, NIDDM T2DM (Moller, D. E., "New drug targets for Type 2 diabetes and the metabolic syndrome" *Nature* 414; 821-827, (2001)): (A) Insulin secretagogues, including sulphonyl-ureas (e.g., glipizide, glimepiride, glyburide) and meglitinides (e.g., nateglinide and repaglinide) enhance secretion of insulin by acting on the pancreatic beta-cells. While this therapy can decrease blood glucose level, it has limited efficacy and tolerability, causes weight gain and often induces hypoglycemia. (B) Biguanides (e.g., metformin) are thought to act primarily by decreasing hepatic glucose production. Biguanides often cause gastrointestinal disturbances and lactic acidosis, further limiting their use. (C) Inhibitors of alpha-glucosidase (e.g., acarbose) decrease intestinal glucose absorption. These agents often cause gastrointestinal disturbances. (D) Thiazolidinediones (e.g., pioglitazone, rosiglitazone) act on a specific receptor (peroxisome proliferator-activated receptor-gamma) in the liver, muscle and fat tissues. They regulate lipid metabolism subsequently enhancing the response of these tissues to the actions of insulin. Frequent use of these drugs may lead to weight gain and may induce edema and anemia. (E) Insulin is used in more severe cases, either alone or in combination with the above agents.

Ideally, an effective new treatment for NIDDM T2DM would meet the following criteria: (a) it would not have significant side effects including induction of hypoglycemia; (b) it would not cause weight gain; (c) it would at least partially replace insulin by acting via mechanism(s) that are independent from the actions of insulin; (d) it would desirably be metabolically stable to allow less frequent usage; and (e) it would be usable in combination with tolerable amounts of any of the categories of drugs listed herein.

A number of publications have appeared which disclose non-peptide compounds which act at the glucagon receptor. For example, WO 03/048109, WO 2004/002480, WO 2005/123668, WO 2005/118542, WO 2006/086488, WO 2006/120667, WO 2007/106181, WO 2007/114855, WO 2007/120270, WO 2007/123581 and Kurukulasuriya et al. *Bioorganic & Medicinal Chemistry Letters*, 2004, 14(9), 2047-2050 each disclose non-peptide compounds that act as glucagon receptor antagonists. Although investigations are

on-going, there still exists a need for a more effective and safe therapeutic treatment for diabetes, particularly NIDDM.

## DEFINITIONS

As used herein, the term "alkyl" refers to a hydrocarbon radical of the general formula  $C_nH_{2n+1}$ . The alkane radical may be straight or branched. For example, the term "(C<sub>1</sub>-C<sub>6</sub>)alkyl" refers to a monovalent, straight, or branched aliphatic group containing 1 to 6 carbon atoms (e.g., methyl, ethyl, n-propyl, i-propyl, n-butyl, i-butyl, s-butyl, t-butyl, n-pentyl, 1-methylbutyl, 2-methylbutyl, 3-methylbutyl, neopentyl, 3,3-dimethylpropyl, hexyl, 2-methylpentyl, and the like). Similarly, the alkyl portion (i.e., alkyl moiety) of an alkoxy, acyl (e.g., alkanoyl), alkylamino, dialkylamino, alkylsulfonyle, and alkylthio group have the same definition as above. When indicated as being "optionally substituted", the alkane radical or alkyl moiety may be unsubstituted or substituted with one or more substituents (generally, one to three substituents except in the case of halogen substituents such as perchloro or perfluoroalkyls).

The term "cycloalkyl" refers to nonaromatic rings that are fully hydrogenated and may exist as a single ring, bicyclic ring or a spiral ring. Unless specified otherwise, the carbo-

cyclic ring is generally a 3- to 8-membered ring. For example, (C<sub>3</sub>-C<sub>7</sub>)cycloalkyl include groups such as cyclopropyl, cyclobutyl, cyclopentyl, cyclohexyl, cyclohexenyl, cycloheptyl, norbornyl (bicyclo[2.2.1]heptyl) and the like. In certain embodiments one or more of the carbon atoms in a cycloalkyl may be replaced with a heteroatom as specified, such as with an O, S, NH or N-alkyl.

The phrase "5 membered heteroaryl" or "6 membered heteroaryl" means a radical of a 5 or 6 membered heteroaromatic ring, respectively. The heteroaromatic ring can contain 1 to 4 heteroatoms selected from N, O and S. 5 to 6 membered heteroaryl groups include pyrrolyl, furanyl, thienyl, imidazolyl, thiazolyl, oxazolyl, triazolyl, tetrazolyl, pyridinyl, pyrimidinyl, pyrazinyl, triazinyl and the like. Preferred 5 to 6 membered heteroaryl groups include pyrazolyl, imidazolyl, pyridinyl, pyrimidinyl or pyrazinyl. The heteroaryl group may be fused to another ring when specified. For example, a 5 membered heteroaryl such as a pyrazole may be fused with a phenyl to provide an indazole.

The phrase "therapeutically effective amount" means an amount of a compound of the present invention that (i) treats or prevents the particular disease, condition, or disorder, (ii) attenuates, ameliorates, or eliminates one or more symptoms of the particular disease, condition, or disorder, or (iii) prevents or delays the onset of one or more symptoms of the particular disease, condition, or disorder described herein.

The term "animal" refers to humans (male or female), companion animals (e.g., dogs, cats and horses), food-source animals, zoo animals, marine animals, birds and other similar animal species. "Edible animals" refers to food-source animals such as cows, pigs, sheep and poultry.

The phrase "pharmaceutically acceptable" indicates that the substance or composition must be compatible chemically and/or toxicologically, with the other ingredients comprising a formulation, and/or the mammal being treated therewith.

The terms "treating", "treat", or "treatment" embrace both preventative, i.e., prophylactic, and palliative treatment.

The terms "modulated" or "modulating", or "modulate(s)", as used herein, unless otherwise indicated, refers to the changes in activity of the glucagon receptor as a result of action of the compounds of the present invention.

The terms "mediated" or "mediating" or "mediate(s)", as used herein, unless otherwise indicated, refers to the treatment or prevention the particular disease, condition, or disorder, (ii) attenuation, amelioration, or elimination of one or more symptoms of the particular disease, condition, or disorder, or (iii) prevention or delay of the onset of one or more symptoms of the particular disease, condition, or disorder described herein, by modulation of glucagon.

The term "compounds of the present invention" (unless specifically identified otherwise) refer to compounds of Formula I and any pharmaceutically acceptable salts of the compounds, as well as, all stereoisomers (including diastereoisomers and enantiomers), tautomers, conformational isomers, and isotopically labeled compounds. Hydrates and solvates of the compounds of the present invention are considered compositions of the present invention, wherein the compound is in association with water or solvent, respectively.

## DETAILED DESCRIPTION

For illustrative purposes, the reaction schemes depicted below provide potential routes for synthesizing the compounds of the present invention as well as key intermediates. For a more detailed description of the individual reaction steps, see the Examples section below. Those skilled in the art will appreciate that other synthetic routes may be used to synthesize the inventive compounds. Although specific starting materials and reagents are depicted in the schemes and discussed below, other starting materials and reagents can be easily substituted to provide a variety of derivatives and/or reaction conditions. In addition, many of the compounds prepared by the methods described below can be further modified in light of this disclosure using conventional chemistry well known to those skilled in the art.

In the preparation of compounds of the present invention, protection of remote functionality (e.g., primary or secondary amine) of intermediates may be necessary. The need for such protection will vary depending on the nature of the remote functionality and the conditions of the preparation methods. Suitable amino-protecting groups (NH-Pg) include acetyl, trifluoroacetyl, t-butoxycarbonyl (BOC), benzyloxycarbonyl (CBz) and 9-fluorenylmethyloxycarbonyl (Fmoc). Similarly, a "hydroxy-protecting group" refers to a substituent of a hydroxy group that blocks or protects the hydroxy functionality. Suitable hydroxyl-protecting groups (O-Pg) include for example, allyl, acetyl, silyl, benzyl, para-methoxybenzyl, trityl, and the like. The need for such protection is readily determined by one skilled in the art. For a general description of protecting groups and their use, see T. W. Greene, *Protective Groups in Organic Synthesis*, John Wiley & Sons, New York, 1991.

Reaction Scheme I outlines the general procedures that can be used to provide compounds of the present invention of Formula I.

## 12

Reaction Scheme I provides a general route which can be employed to prepare compounds of Formula I. More specific details of the transformations depicted are provided in Reaction Schemes II-VII below. It is to be understood that the reaction schemes are illustrative and are not to be construed as a limitation in any manner. In step one of Reaction Scheme I the compound  $R^1-M$  of Formula VII and the compound of Formula VI are coupled. In the compound of Formula VII,  $R^1$  is a 5 membered optionally fused and optionally substituted heteroaryl group. The group M can represent either hydrogen when attached to nitrogen in the heteroaryl group  $R^1$  or an appropriate metal species when attached to a carbon in the heteroaryl group  $R^1$ . When M is a metal attached to a carbon in the group  $R^1$  the coupling reaction can be carried out using a palladium catalyzed coupling reaction. When M represents hydrogen attached to nitrogen in the heteroaryl  $R^1$  group the nucleophilic displacement reaction to form the compound of Formula V can be carried out in an appropriate solvent in the presence of a base. In the compound of Formula VI Lg is an appropriate leaving group, such as a halide or triflate. The compound of Formula V can then be reacted with the compound of Formula IV to provide the compound of Formula III. In the compound of Formula V L' represents a precursor group which is, along with  $R''$  in the compound of Formula IV is converted into the linker L in the compound of Formula III. The compound of Formula III can then be hydrolyzed to provide the free acid of Formula II which can then be subjected to an amide coupling reaction with the amine  $R^3R^2NH$ , followed by deprotection if necessary to provide the compound of Formula I. The group  $R^{3'}$  in the amine  $R^3R^2NH$  can represent either  $R^3$  itself or a protected version of  $R^3$  which can be subsequently deprotected to provide  $R^3$ .

Reaction Scheme II outlines another general procedure that can be used to provide compounds of the present invention having Formula I.

14

The ester compound of Formula III may be formed by reaction of an appropriate heteroaryl compound  $R^1-H$  or a metallated heteroaryl compound  $R^1-M$  with the compound of Formula IIIa. The reaction with  $R^1-H$  can be employed when the hydrogen depicted in  $R^1-H$  is attached to nitrogen in the  $R^1$  heteroaryl group. The reaction can be carried out in an appropriate solvent such as dimethyl sulfoxide and a base such as potassium carbonate in the presence of copper(I) iodide. The reaction between the compound of Formula IIIa and  $R^1-M$  can be carried out by a palladium catalysed coupling reaction. Preferably, the reaction is carried out between the boronate ester  $R^1-M$  (where M is  $B(OR)_2$  and R' is H or lower alkyl or both R's together form an appropriate cyclic group) and the compound of Formula IIIa (wherein Lg is  $OSO_2CF_3$ , Cl, Br or I) using a suitable palladium catalyst, a suitable phosphine ligand and a suitable base in the presence of a suitable solvent at a temperature of typically from room temperature up to around reflux (or at temperatures above the boiling point of the solvent e.g. 120° C. using microwave conditions).

A suitable palladium catalyst is tris(dibenzylideneacetone)dipalladium, bis(dibenzylideneacetone) palladium, palladium acetate or (1,1'-bis(diphenylphosphino) ferrocene)dichloropalladium. A suitable phosphine ligand is tricyclohexylphosphine, triphenylphosphine or 2-dicyclohexylphosphino-2',6'-dimethoxybiphenyl. A suitable base is sodium carbonate, potassium carbonate, potassium phosphate or sodium hydrogen carbonate and solvents are DME, 1,4-dioxane or THF/water.

Alternatively, the cross coupling may be carried out between the trimethyl stannane of general Formula  $R^1-M$  (wherein M is  $SnMe_3$ ) and the compound of Formula IIIa using a suitable catalyst, such as tetrakis(triphenylphosphine)palladium, an optional copper (I) source, such as copper (I) chloride, a suitable base, such as cesium fluoride, and a suitable solvent, such as N,N-dimethylformamide, at a temperature of typically around 80° C. to 120° C. Further alternative methods using metallated compounds  $R^1-M$  (where M is  $MgX'$  or  $ZnX'$  and  $X'$  is a halide) with the derivative IIIa using a suitable palladium catalyst, a suitable phosphine base, an optional copper (I) source, and a suitable base in the presence of a suitable solvent at a temperature of typically around reflux, can also be employed.

Suitable palladium catalysts are tris(dibenzylideneacetone)dipalladium, bis(dibenzylidene acetone)palladium, palladium acetate or (1,1'-bis(diphenylphosphino)ferrocene) dichloropalladium. Suitable phosphine bases are tricyclohexylphosphine or 2-dicyclohexylphosphino-2',6'-dimethoxybiphenyl. A suitable copper (I) source is copper (I) chloride. Suitable bases are potassium carbonate or sodium hydrogen carbonate. Suitable solvents are DME, 1,4-dioxane or THF/water.

The compound of Formula III then undergoes hydrolysis to provide the compound of Formula II. Depending on which R group is present in the ester of Formula III, appropriate acid or base catalyzed hydrolysis can be carried out to provide the corresponding free acid in the compound of Formula II. For example, when R represents methyl, hydrolysis is typically carried out with aqueous sodium hydroxide or lithium hydroxide in a mixture of methanol and

tetrahydrofuran at a temperature from room temperature up to 80° C. for 15 minutes to 24 hours.

Conversion of the compound of Formula II to provide the compound of Formula I can be carried out using standard amide coupling conditions. Amide coupling is carried out using standard literature conditions. The acid of Formula II can be converted to the corresponding acid chloride using a suitable chlorinating agent, such as oxalyl chloride or thionyl chloride, in a suitable solvent, such as dichloromethane or toluene, optionally in the presence of catalytic DMF, at a suitable temperature, typically of between 0° C. and room temperature. The acid chloride can then be reacted with the amine of generic formula  $R^3-NH_2$  in the presence of a base, such as triethylamine or diisopropylethylamine, in a suitable solvent, such as dichloromethane or toluene, at a temperature of between 0° C. and room temperature.  $R^3$  can represent either  $R^3$  itself or a protected version of  $R^3$  which can be subsequently deprotected to provide  $R^3$ . Alternatively, the acid of Formula II can be converted to a suitable activated species with a coupling agent, such as EDCI.HCl, HBTU, HATU, PyBop, DCC, or CDI, in a suitable solvent, such as dichloromethane, acetonitrile or DMF. In the presence of EDCI.HCl, HOBT is typically added. EDCI is 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide; HBTU is O-Benzotriazole-N,N,N',N'-tetramethyluronium hexafluorophosphate; HATU is O-(7-Azabenzotriazol-1-yl)-N,N,N',N'-tetramethyluronium hexafluorophosphate; PyBop is Benzotriazol-1-yloxytripyrrolidinophosphonium hexafluorophosphate; DCC is dicyclohexylcarbodiimide; CDI is N,N'-carbonyldiimidazole and HOBT is 1-hydroxy benzotriazole. A suitable base, such as triethylamine or diisopropylethylamine, is also used and the reaction is typically carried out at room temperature. In the instance where  $R^3$  represents a protected version of  $R^3$ , subsequent deprotection can then be carried out by methods known in the art to provide  $R^3$ . For example, when  $R^3$  is an ester, appropriate acid or base catalyzed hydrolysis can be carried out to provide the corresponding free acid in the compound of Formula I.

Reaction Scheme III outlines the general procedures one could use to provide compounds of the present invention having Formula Ia. The compounds of Formula Ia are of Formula I wherein L is  $-C(R^5)-X-$ , X is NH and  $R^2$  is H.

halide such as magnesium chloride or magnesium bromide. The reaction is carried out in an appropriate solvent such as tetrahydrofuran or a mixture of tetrahydrofuran and diethyl ether. The reaction is typically carried out at 0° C. to 100° C. and microwave irradiation of the reaction mixture is preferred. Upon completion of the Grignard reaction the reaction mixture is then subjected to reduction using an appropriate reducing agent such as sodium borohydride in an appropriate solvent such as methanol to provide the amine compound of Formula IVa. The compound of Formula IVa is then converted to the compound of Formula Ia as previously described for Reaction Scheme II.

Reaction Scheme IV provides the preparation of compounds where L is —XCHR<sup>5</sup>— and X is NH as depicted.

The nitrile of Formula Va is reacted with an appropriate Grignard reagent R<sup>5</sup>-M wherein M represents a magnesium

50 The amine of Formula IVb can be prepared by reduction, such as by hydrogenation, of the corresponding nitro derivative. The amine of Formula IVb can be converted to the compound of Formula IIIb by two methods. The first method involves reaction of the amine with the aldehyde of Formula IVb' followed by alkylation of the resulting aldimine with an appropriate alkylating reagent R<sup>5</sup>-M of Formula IVb'. The reaction of the amine of Formula IVb with the aldehyde of Formula IVb' to provide the corresponding aldimine is carried out in an appropriate solvent, such as toluene, typically in the presence of molecular sieves, at a temperature from room temperature up to 100° C. for a period of 1 to 24 hours. The reaction mixture containing the aldimine can be filtered and concentrated. The resulting residue can then be redissolved in a solvent appropriate for the alkylation reaction, such as tetrahydrofuran. Typically, an appropriate metallated alkylating agent, such as a Grignard reagent R<sup>5</sup>-M of Formula IVb' where M represents a metal

17

such as a magnesium halide is employed. The alkylation reaction can be carried out at a temperature of 0° C. to 60° C. for a period of 1 to 24 hours to provide the compound of Formula IIIb. When R<sup>5</sup>-M represents a Grignard reagent addition of zinc chloride to the reaction mixture may be desirable to increase the yield of the compound of Formula IIIb (see Ishihara, K. et al.; *JACS*, 2006, 128, 9998).

Alternatively, the compound of Formula IIIb can be prepared by reaction of an amine of Formula IVb and a ketone of Formula IVb'" followed by reduction of the resulting imine. The reaction can be carried out under typical reductive amination conditions to provide the compound of Formula IIIb. For example, the amine of Formula IVb and ketone IVb'" in an appropriate solvent such as dimethoxyethane and in the presence of molecular sieves and para-toluene sulfonic acid can be reacted at room temperature up to 120° C. (sealed tube) for 1 to 24 hours. The reaction mixture can then be allowed to cool to room temperature and be treated with an appropriate reducing agent, such as sodium cyanoborohydride in methanol, and in the presence of acetic acid for 1 to 24 hours to provide the compound of Formula IIIb.

The compound of Formula IIIb can be hydrolyzed to provide the free acid compound of Formula IIb by methods as previously described for the preparation of the compound of Formula IIa in Reaction Scheme II. The free acid compound of Formula IIb can then undergo amide coupling conditions followed by deprotection if necessary to provide the compound of Formula Ib as previously described for the conversion of the compound of Formula IIa to Formula Ia in Reaction Scheme II.

Reaction Scheme V outlines the general procedures that can be used to provide compounds of the present invention having Formula Ic. The compounds of Formula Ic are of Formula I wherein L is —X—C(R<sup>5</sup>)—, X is O and R<sup>2</sup> is H.

The compound of Formula IVc is prepared by reaction of an aldehyde of Formula Vc with an appropriate metallated alkylating compound R<sup>5</sup>-M (Vc'). Typically, R<sup>5</sup>-M is a Grignard reagent in which M represents a magnesium halide, such as magnesium chloride or magnesium bromide. The reaction is carried out in an appropriate solvent, such as tetrahydrofuran, at a temperature from about -78° C. to room temperature for a period of 15 minutes to 24 hours to provide the alcohol of Formula IVc. The alcohol IVc is then coupled with the phenol of Formula IVc' using phenolic ether Mitsunobu reaction conditions (see e.g Mitsunobu, O.; *Synthesis*, 1981, 1; Lepore, S. D. et al. *J. Org. Chem.*, 2003, 68(21), 8261-8263) to provide the compound of Formula IIIc. This reaction is typically carried out in an appropriate solvent such as tetrahydrofuran in the presence of an appropriate coupling reagent such as diethylazodicarboxylate (DEAD) or diisopropylazodicarboxylate (DIAD) and a phosphine ligand such as triphenylphosphine. The reaction is typically run at a temperature from about 0° C. to room temperature for 1 to 24 hours. The compound IIIc can then be hydrolyzed to the compound of Formula IIc followed by amide formation and deprotection, as necessary, to provide the compound of Formula Ic as previously described for the corresponding steps in Reaction Scheme II.

Reaction Scheme VI outlines the general procedures that can be used to provide compounds of the present invention having Formula Id. The compounds of Formula Id are of Formula I wherein L is —C(R<sup>5</sup>)—X—, X is O and R<sup>2</sup> is H.

The compound of Formula Id is prepared in an analogous manner to the preparation of the compound of Formula Ic in Reaction Scheme V by substituting the compounds of Formula Vd, Vd', IVd, IVd', IIId and IId for the compounds Vc, Vc', IVc, IVc', IIId and IIc as previously described.

Reaction Scheme VII outlines the general procedures one could use to provide compounds of the present invention having Formula Ia. The compounds of Formula Ia are of Formula I wherein R<sup>1</sup> is in the para position, L is —X—C(R<sup>5</sup>)—, X is CH<sub>2</sub> and R<sup>2</sup> is H.

The phosphonium bromide compound of Formula VIIe may be treated with an appropriate base and then reacted with the ketone derivative of Formula VIIe' to provide the olefinic compound of Formula VIIe. The compound of Formula VIIe is typically treated with a base such as lithium bis(trimethylsilyl)amide (LHMDS) in an appropriate solvent such as toluene at −78° C. up to room temperature. Other bases that can be employed include lithium amides such as lithium diisopropylamide (LDA), lithium 2,2,6,6-tetramethyl piperide (LiTMP) or lithium diethyl amide as well as alkyl lithiums such as methyl lithium or n-butyl lithium.

The compound of Formula VIIe can then be reacted with the heteroaryl compound R<sup>1</sup>-M (VIIe' wherein M is hydrogen when attached to nitrogen or an appropriate metal when attached to carbon). When M is a metal attached to a carbon in the heteroaryl represented by R<sup>1</sup> the reaction is typically a palladium catalyzed coupling reaction, as was described previously for the first step in Reaction Scheme II to provide the compound of Formula Ve. When M is hydrogen attached to nitrogen in the heteroaryl R<sup>1</sup>, the nucleophilic substitution reaction is typically carried out in an appropriate solvent in the presence of a base. The compound of Formula Ve is then subjected to hydrolysis, typically in methanol and tetrahydrofuran using sodium hydroxide as base at 0° C. to room temperature for a period of 1 to 24 hours to provide the free acid of formula IVe. The free acid of Formula IVe can then be reacted with the amine R<sup>3</sup>'—NH<sub>2</sub> using the amide coupling conditions previously described for Reaction Scheme II to provide the compound of Formula IIIe. The compound of Formula IIIe is then subjected to hydrogenation to reduce the olefinic moiety and provide the compound of Formula IIe. The hydrogenation is typically carried out in the presence of an appropriate hydrogenation catalyst, such as 10% palladium on carbon (Pd/C), in an appropriate solvent such as methanol at a temperature from room temperature up to 50° C. Hydrogenation apparatus such as the ThalesNano H-Cube® hydrogenator (ThalesNano, Budapest, Hungary) with a 10% Pd/C cartridge can be employed for this step. The compound of Formula IIe can then be deprotected as necessary and as previously described for Reaction Scheme II to provide the compound of Formula Ia.

Reaction Scheme VIII outlines another general procedure that can be used to provide compounds of the present invention having Formula Ic. The compounds of Formula Ic are of Formula I wherein L is —X—C(R<sup>5</sup>)—, X is O and R<sup>2</sup> is H.

21

The compound of Formula Vf in which Lg is an appropriate halide, preferably iodide, and R<sup>3'</sup> represents a protected R<sup>3</sup> group (such as an ester of an appropriate R<sup>3</sup> carboxylic acid group) can be treated with magnesium in an appropriate solvent to provide the corresponding Grignard reagent. The Grignard reagent can then be reacted with the aldehyde R<sup>5</sup>—CHO to provide the compound of Formula IVf. The compound of Formula IVf can undergo Mitsunobu coupling with the compound of Formula IVc' as previously described for Reaction Scheme V to provide the compound of Formula IIIf. Deprotection of the compound of Formula IIIf, for example by hydrolysis of an ester as previously described, then provides the compound of Formula Ic.

The compounds of the present invention may be isolated and used per se, or when possible, in the form of its pharmaceutically acceptable salt. The term "salts" refers to inorganic and organic salts of a compound of the present invention. These salts can be prepared in situ during the final isolation and purification of a compound, or by separately reacting the compound with a suitable organic or inorganic acid or base and isolating the salt thus formed. Representative salts include the hydrobromide, hydrochloride, hydroiodide, sulfate, bisulfate, nitrate, acetate, trifluoroacetate, oxalate, besylate, palmitate, pamoate, malonate, stearate, laurate, malate, borate, benzoate, lactate, phosphate, hexafluorophosphate, benzene sulfonate, tosylate, formate, citrate, maleate, fumarate, succinate, tartrate, naphthylate, mesylate, glucoheptonate, lactobionate, and laurylsulphonate salts, and the like. These may include cations based on the alkali and alkaline earth metals, such as sodium, lithium, potassium, calcium, magnesium, and the like, as well as non-toxic ammonium, quaternary ammonium, and amine cations including, but not limited to, ammonium, tetramethylammonium, tetraethylammonium, methylamine, dimethylamine, trimethylamine, triethylamine, ethylamine, and the like. See, e.g., Berge, et al., *J. Pharm. Sci.*, 66, 1-19 (1977).

22

The compounds of the present invention may contain asymmetric or chiral centers, and, therefore, exist in different stereoisomeric forms. Unless specified otherwise, it is intended that all stereoisomeric forms of the compounds of the present invention as well as mixtures thereof, including racemic mixtures, form part of the present invention. In addition, the present invention embraces all geometric and positional isomers. For example, if a compound of the present invention incorporates a double bond or a fused ring, both the cis- and trans-forms, as well as mixtures, are embraced within the scope of the invention.

Diastereomeric mixtures can be separated into their individual diastereoisomers on the basis of their physical chemical differences by methods well known to those skilled in the art, such as by chromatography and/or fractional crystallization. Enantiomers can be separated by converting the enantiomeric mixture into a diastereomeric mixture by reaction with an appropriate optically active compound (e.g., chiral auxiliary such as a chiral alcohol or Mosher's acid chloride), separating the diastereoisomers and converting (e.g., hydrolyzing) the individual diastereoisomers to the corresponding pure enantiomers. Also, some of the compounds of the present invention may be atropisomers (e.g., substituted biaryls) and are considered as part of this invention. Enantiomers can also be separated by use of a chiral HPLC column. Alternatively, the specific stereoisomers may be synthesized by using an optically active starting material, by asymmetric synthesis using optically active reagents, substrates, catalysts or solvents, or by converting one stereoisomer into the other by asymmetric transformation.

It is also possible that the intermediates and compounds of the present invention may exist in different tautomeric forms, and all such forms are embraced within the scope of the invention. The term "tautomer" or "tautomeric form" refers to structural isomers of different energies which are interconvertible via a low energy barrier. For example, proton tautomers (also known as prototropic tautomers) include interconversions via migration of a proton, such as keto-enol and imine-enamine isomerizations. A specific example of a proton tautomer is the imidazole moiety where the proton may migrate between the two ring nitrogens. Valence tautomers include interconversions by reorganization of some of the bonding electrons. For example, the pyrimidone ring of this invention may also exist in its hydroxy pyrimidine form. Both such forms are included in the compounds of Formula I.

Certain compounds of the present invention may exist in different stable conformational forms which may be separable. Torsional asymmetry due to restricted rotation about an asymmetric single bond, for example, because of steric hindrance or ring strain, may permit separation of different conformers.

The present invention also embraces isotopically-labeled compounds of the present invention which are identical to those recited herein, but for the fact that one or more atoms are replaced by an atom having an atomic mass or mass number different from the atomic mass or mass number usually found in nature. Examples of isotopes that can be incorporated into compounds of the invention include isotopes of hydrogen, carbon, nitrogen, oxygen, phosphorus, sulfur, fluorine, iodine, and chlorine, such as <sup>2</sup>H, <sup>3</sup>H, <sup>11</sup>C, <sup>13</sup>C, <sup>14</sup>C, <sup>15</sup>N, <sup>15</sup>N, <sup>15</sup>O, <sup>17</sup>O, <sup>18</sup>O, <sup>31</sup>F, <sup>32</sup>F, <sup>35</sup>S, <sup>18</sup>F, <sup>123</sup>I, <sup>125</sup>I and <sup>36</sup>Cl, respectively.

Certain isotopically-labeled compounds of the present invention (e.g., those labeled with <sup>3</sup>H and <sup>14</sup>C) are useful in compound and/or substrate tissue distribution assays. Tritiated (i.e., <sup>3</sup>H) and carbon-14 (i.e., <sup>14</sup>C) isotopes are particu-

larly preferred for their ease of preparation and detectability. Further, substitution with heavier isotopes such as deuterium (i.e.,  $^2\text{H}$ ) may afford certain therapeutic advantages resulting from greater metabolic stability (e.g., increased in vivo half-life or reduced dosage requirements) and hence may be preferred in some circumstances. Positron emitting isotopes such as  $^{15}\text{O}$ ,  $^{13}\text{N}$ ,  $^{11}\text{C}$ , and  $^{18}\text{F}$  are useful for positron emission tomography (PET) studies to examine substrate occupancy. Isotopically labeled compounds of the present invention can generally be prepared by following procedures analogous to those disclosed in the Schemes and/or in the Examples herein below, by substituting an isotopically labeled reagent for a non-isotopically labeled reagent.

Certain compounds of the present invention may exist in more than one crystal form (generally referred to as "polymorphs"). Polymorphs may be prepared by crystallization under various conditions, for example, using different solvents or different solvent mixtures for recrystallization; crystallization at different temperatures; and/or various modes of cooling, ranging from very fast to very slow cooling during crystallization. Polymorphs may also be obtained by heating or melting the compound of the present invention followed by gradual or fast cooling. The presence of polymorphs may be determined by solid probe NMR spectroscopy, IR spectroscopy, differential scanning calorimetry, powder X-ray diffraction or such other techniques.

Compounds of the present invention are useful for treating diseases, conditions and/or disorders modulated by glucagon; therefore, another embodiment of the present invention is a pharmaceutical composition comprising a therapeutically effective amount of a compound of the present invention and a pharmaceutically acceptable excipient, diluent or carrier. The compounds of the present invention (including the compositions and processes used therein) may also be used in the manufacture of a medicament for the therapeutic applications described herein.

A typical formulation is prepared by mixing a compound of the present invention and a carrier, diluent or excipient. Suitable carriers, diluents and excipients are well known to those skilled in the art and include materials such as carbohydrates, waxes, water soluble and/or swellable polymers, hydrophilic or hydrophobic materials, gelatin, oils, solvents, water, and the like. The particular carrier, diluent or excipient used will depend upon the means and purpose for which the compound of the present invention is being applied. Solvents are generally selected based on solvents recognized by persons skilled in the art as safe (GRAS) to be administered to a mammal. In general, safe solvents are non-toxic aqueous solvents such as water and other non-toxic solvents that are soluble or miscible in water. Suitable aqueous solvents include water, ethanol, propylene glycol, polyethylene glycols (e.g., PEG400, PEG300), etc. and mixtures thereof. The formulations may also include one or more buffers, stabilizing agents, surfactants, wetting agents, lubricating agents, emulsifiers, suspending agents, preservatives, antioxidants, opaquing agents, glidants, processing aids, colorants, sweeteners, perfuming agents, flavoring agents and other known additives to provide an elegant presentation of the drug (i.e., a compound of the present invention or pharmaceutical composition thereof) or aid in the manufacturing of the pharmaceutical product (i.e., medicament).

The formulations may be prepared using conventional dissolution and mixing procedures. For example, the bulk drug substance (i.e., compound of the present invention or stabilized form of the compound (e.g., complex with a cyclodextrin derivative or other known complexation agent)) is dissolved in a suitable solvent in the presence of

one or more of the excipients described above. The compound of the present invention is typically formulated into pharmaceutical dosage forms to provide an easily controllable dosage of the drug and to give the patient an elegant and easily handleable product.

The pharmaceutical compositions also include solvates and hydrates of the compounds of Formula I. The term "solvate" refers to a molecular complex of a compound represented by Formula I (including pharmaceutically acceptable salts thereof) with one or more solvent molecules. Such solvent molecules are those commonly used in the pharmaceutical art, which are known to be innocuous to the recipient, e.g., water, ethanol, ethylene glycol, and the like. The term "hydrate" refers to the complex where the solvent molecule is water. The solvates and/or hydrates preferably exist in crystalline form. Other solvents may be used as intermediate solvates in the preparation of more desirable solvates, such as methanol, methyl t-butyl ether, ethyl acetate, methyl acetate, (S)-propylene glycol, (R)-propylene glycol, 1,4-butyne-diol, and the like.

The pharmaceutical composition (or formulation) for application may be packaged in a variety of ways depending upon the method used for administering the drug. Generally, an article for distribution includes a container having deposited therein the pharmaceutical formulation in an appropriate form. Suitable containers are well-known to those skilled in the art and include materials such as bottles (plastic and glass), sachets, ampoules, plastic bags, metal cylinders, and the like. The container may also include a tamper-proof assemblage to prevent indiscreet access to the contents of the package. In addition, the container has deposited thereon a label that describes the contents of the container. The label may also include appropriate warnings.

The present invention further provides a method of treating diseases, conditions and/or disorders modulated by glucagon in an animal that includes administering to an animal in need of such treatment a therapeutically effective amount of a compound of the present invention or a pharmaceutical composition comprising an effective amount of a compound of the present invention and a pharmaceutically acceptable excipient, diluent, or carrier. The method is particularly useful for treating diseases, conditions and/or disorders that benefit from the modulation of glucagon which include: eating disorders (e.g., binge eating disorder, anorexia, bulimia, weight loss or control and obesity), prevention of obesity and insulin resistance.

One aspect of the present invention is the treatment of obesity, and obesity-related disorders (e.g., overweight, weight gain, or weight maintenance).

Obesity and overweight are generally defined by body mass index (BMI), which is correlated with total body fat and estimates the relative risk of disease. BMI is calculated by weight in kilograms divided by height in meters squared ( $\text{kg}/\text{m}^2$ ). Overweight is typically defined as a BMI of 25-29.9  $\text{kg}/\text{m}^2$ , and obesity is typically defined as a BMI of 30  $\text{kg}/\text{m}^2$ . See, e.g., National Heart, Lung, and Blood Institute, Clinical Guidelines on the Identification, Evaluation, and Treatment of Overweight and Obesity in Adults, The Evidence Report, Washington, D.C.: U.S. Department of Health and Human Services, NIH publication no. 98-4083 (1998).

Another aspect of the present invention is for the treatment or delaying the progression or onset of diabetes or diabetes-related disorders including Type 1 (insulin-dependent diabetes mellitus, also referred to as "IDDM") and Type 2 (noninsulin-dependent diabetes mellitus, also referred to as "NIDDM") diabetes, impaired glucose tolerance, insulin

resistance, hyperglycemia, and diabetic complications (such as atherosclerosis, coronary heart disease, stroke, peripheral vascular disease, nephropathy, hypertension, neuropathy, and retinopathy).

Yet another aspect of the present invention is the treatment of diabetes- or obesity-related co-morbidities, such as metabolic syndrome. Metabolic syndrome includes diseases, conditions or disorders such as dyslipidemia, hypertension, insulin resistance, diabetes (e.g., Type 2 diabetes), weight gain, coronary artery disease and heart failure. For more detailed information on Metabolic Syndrome, see, e.g., Zimmet, P. Z., et al., "The Metabolic Syndrome: Perhaps an Etiologic Mystery but Far From a Myth Where Does the International Diabetes Federation Stand?," *Diabetes & Endocrinology*, 7(2), (2005); and Alberti, K. G., et al., "The Metabolic Syndrome A New Worldwide Definition," *Lancet*, 366, 1059-62 (2005). Preferably, administration of the compounds of the present invention provides a statistically significant ( $p < 0.05$ ) reduction in at least one cardiovascular disease risk factor, such as lowering of plasma leptin, C-reactive protein (CRP) and/or cholesterol, as compared to a vehicle control containing no drug. The administration of compounds of the present invention may also provide a statistically significant ( $p < 0.05$ ) reduction in glucose serum levels.

In yet another aspect of the present invention, the condition treated is impaired glucose tolerance, hyperglycemia, diabetic complications such as sugar cataracts, diabetic neuropathy, diabetic nephropathy, diabetic retinopathy and diabetic cardiomyopathy, anorexia nervosa, bulimia, cachexia, hyperuricemia, hyperinsulinemia, hypercholesterolemia, hyperlipidemia, dyslipidemia, mixed dyslipidemia, hypertriglyceridemia, nonalcoholic fatty liver disease, atherosclerosis, arteriosclerosis, acute heart failure, congestive heart failure, coronary artery disease, cardiomyopathy, myocardial infarction, angina pectoris, hypertension, hypotension, stroke, ischemia, ischemic reperfusion injury, aneurysm, restenosis, vascular stenosis, solid tumors, skin cancer, melanoma, lymphoma, breast cancer, lung cancer, colorectal cancer, stomach cancer, esophageal cancer, pancreatic cancer, prostate cancer, kidney cancer, liver cancer, bladder cancer, cervical cancer, uterine cancer, testicular cancer and ovarian cancer.

The present invention also relates to therapeutic methods for treating the above described conditions in a mammal, including a human, wherein a compound of Formula I of this invention is administered as part of an appropriate dosage regimen designed to obtain the benefits of the therapy. The appropriate dosage regimen, the amount of each dose administered and the intervals between doses of the compound will depend upon the compound of formula (I) of this invention being used, the type of pharmaceutical compositions being used, the characteristics of the subject being treated and the severity of the conditions.

In general, an effective dosage for the compounds of the present invention is in the range of 0.01 mg/kg/day to 30 mg/kg/day, preferably 0.01 mg/kg/day to 5 mg/kg/day of active compound in single or divided doses. However, some variability in the general dosage range may be required depending upon the age and weight of the subject being treated, the intended route of administration, the particular compound being administered and the like. The determination of dosage ranges and optimal dosages for a particular patient is well within the ability of one of ordinary skill in the art having the benefit of the instant disclosure. Practitioners will appreciate that "kg" refers to the weight of the patient measured in kilograms.

The compounds or compositions of this invention may be administered in single (e.g., once daily) or multiple doses or via constant infusion. The compounds of this invention may also be administered alone or in combination with pharmaceutically acceptable carriers, vehicles or diluents, in either single or multiple doses. Suitable pharmaceutical carriers, vehicles and diluents include inert solid diluents or fillers, sterile aqueous solutions and various organic solvents.

The compounds or compositions of the present invention may be administered to a subject in need of treatment by a variety of conventional routes of administration, including orally and parenterally, (e.g., intravenously, subcutaneously or intramedullary). Further, the pharmaceutical compositions of this invention may be administered intranasally, as a suppository, or using a "flash" formulation, i.e., allowing the medication to dissolve in the mouth without the need to use water.

It is also noted that the compounds of the present invention can be used in sustained release, controlled release, and delayed release formulations, which forms are also well known to one of ordinary skill in the art.

The compounds of this invention may also be used in conjunction with other pharmaceutical agents for the treatment of the diseases, conditions and/or disorders described herein. Therefore, methods of treatment that include administering compounds of the present invention in combination with other pharmaceutical agents are also provided. ## General Experimental Procedures

NMR spectra were recorded on a Varian Unity™ 400 (available from Varian Inc., Palo Alto, Calif.) at room temperature at 400 MHz for proton. Chemical shifts are expressed in parts per million ( $\delta$ ) relative to residual solvent as an internal reference. The peak shapes are denoted as follows: s, singlet; d, doublet; dd, doublet of doublet; t, triplet; q, quartet; m, multiplet; bs, broad singlet; 2s, two singlets. Atmospheric pressure chemical ionization mass spectra (APCI) were obtained on a Fisons™ Platform II Spectrometer (carrier gas: acetonitrile: available from Micromass Ltd, Manchester, UK). Chemical ionization mass spectra (CI) were obtained on a Hewlett-Packard™ 5989 instrument (ammonia ionization, PBMS: available from Hewlett-Packard Company, Palo Alto, Calif.). Electrospray ionization mass spectra (ES) were obtained on a Waters™ ZMD instrument (carrier gas: acetonitrile: available from Waters Corp., Milford, Mass.). High resolution mass spectra (HRMS) were obtained on an Agilent™ Model 6210 using time of flight method. Where the intensity of chlorine or bromine-containing ions are described, the expected intensity ratio was observed (approximately 3:1 for <sup>35</sup>Cl/<sup>37</sup>Cl-containing ions and 1:1 for <sup>79</sup>Br/<sup>81</sup>Br-containing ions) and the intensity of only the lower mass ion is given. In some cases only representative <sup>1</sup>H NMR peaks are given. Optical rotations were determined on a PerkinElmer™ 241 polarimeter (available from PerkinElmer Inc., Wellesley, Mass.) using the sodium D line ( $\lambda$ =589 nm) at the indicated temperature and are reported as follows  $[ \alpha ]_D^{temp}$ , concentration (c=g/100 ml), and solvent.

Column chromatography was performed with either Baker™ silica gel (40  $\mu$ m; J.T. Baker, Phillipsburg, N.J.) or Silica Gel 50 (EM Sciences™, Gibbstown, N.J.) in glass columns or in Flash 40 Biotage™ columns (ISC, Inc., Shelton, Conn.) or Biotage™ SNAP cartridge KPsil or Redisp Rf silica (from Teledyne™ Isco™) under low nitrogen pressure. Chiral SFC (supercritical fluid chromatography) was performed on the chiral columns as specified.

Certain solvents and reagents may be referred to using common abbreviations such as DCM for dichloromethane, DMF for dimethylformamide, EtOH for ethanol, EtOAc for ethyl acetate, and MeOH for methanol, for example.

Triethylamine (0.167 mL, 1.20 mmol) was added and the mixture was agitated on an orbital shaker overnight. The reaction mixture was treated with Si-diamine scavenger (ca. 5.0 eq) and the mixture was agitated for 12 hours on an orbital shaker. The reaction was filtered through a plug of silica gel, rinsing with tetrahydrofuran (3 times). The combined organic filtrate was concentrated in vacuo.

In an oven-dried, N<sub>2</sub>-purged round bottom, 4-bromo-3,5-difluoroanisole (500 mg, 2.24 mmol) was dissolved in anhydrous THF (11 mL) and brought to -78° C. nBuLi (0.96 mL, 2.44 M in THF, 2.35 mmol) was added over 2 min. This was stirred for 5 min and then a solution di-tert-butyl azodicarboxylate (542 mg, 2.35 mmol) in anhydrous THF (3 mL) in an oven-dried, N<sub>2</sub>-purged pear flask was added in one portion via syringe. The reaction was removed from the ice bath and allowed to warm to room temperature over 30 min. The reaction, a clear solution, was quenched by the addition of aq. sat. NH<sub>4</sub>Cl. The material was extracted with two portions of ethyl acetate and the combined organics were dried over MgSO<sub>4</sub> and concentrated in vacuo. Purification by silica gel flash chromatography (ethyl acetate in heptane) gave di-tert-butyl 1-(2,6-difluoro-4-methoxyphenyl)hydrazine-1,2-dicarboxylate (0.868 g, impure with ethyl acetate) as a clear oil. <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>,  $\delta$ ): 6.48 (d, J=10.1 Hz, 2H) 3.73-3.85 (m, 3H) 1.36-1.60 (m, 18H).

This suspension was brought to 0° C. and solid NaOMe (87.6 mg, 1.54 mmol) was added. The reaction was stirred overnight allowing the bath to melt. At 21 h, the reaction was a brown solution with some solid present. Trifluoroacetic acid (0.48 mL, 6.19 mmol) was added and the reaction refluxed. At 5 h, the reaction was cooled and partitioned between ethyl acetate and sat. NaHCO<sub>3</sub>. The aqueous was extracted with ethyl acetate and the combined organics dried over MgSO<sub>4</sub>. Purification by silica gel flash chromatography (ethyl acetate in heptane) gave 1-(2,6-difluoro-4-methoxy-phenyl)-4-trifluoromethyl-1H-pyrazole (0.230 g, 59%) as a yellow oil. <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>,  $\delta$ ): 7.97 (s, 1H) 7.89 (s, 1H) 6.64 (d, J=9.4 Hz, 2H) 3.87 (s, 3H); MS (M+1): 279.2.

1-(2,6-Difluoro-4-methoxy-phenyl)-4-trifluoromethyl-1H-pyrazole (278 mg, 0.999 mmol) was dissolved in dichloromethane (3 mL). Boron tribromide (20.0 mL, 1.0 M in DCM, 20.0 mmol) was added and the reaction was refluxed. At 42 h, the reaction was cooled in an ice bath and slowly quenched with methanol. The combined materials were then concentrated and partitioned between ethyl acetate and sat.  $\text{NaHCO}_3$ . The aqueous layer was extracted with ethyl acetate and the combined organics dried over  $\text{MgSO}_4$ . Purification by silica gel flash chromatography (ethyl acetate in heptane) gave 3,5-difluoro-4-(4-trifluoromethyl-pyrazol-1-yl)-phenol (0.231 g, 88%) as a tan oil that solidified upon standing.  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ ,  $\delta$ ): 7.99 (s, 1H) 7.90 (s, 1H) 6.50-6.60 (m, 2H); MS (M+1): 265.2.

Triphenylphosphine (457 mg, 1.74 mmol) was added followed by diazopropyl azodicarboxylate (0.451 mL, 2.18 mmol). This was stirred at room temperature as a yellow solution. At 17 h, the reaction was concentrated. Purification by silica gel flash chromatography (ethyl acetate in heptane) gave impure (+/-)-4-{1-[3,5-difluoro-4-(4-trifluoromethyl-pyrazol-1-yl)-phenoxy]-butyl}-benzoic acid ethyl ester (0.411 g) as a clear oil.  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ ,  $\delta$ ): 8.06 (d,  $J=8.2$  Hz, 2H) 7.93 (s, 1H) 7.82 (s, 1H) 7.39 (d,  $J=8.4$  Hz, 2H) 6.54 (d,  $J=9.4$  Hz, 2H) 5.15 (dd,  $J=7.6, 5.3$  Hz, 1H) 4.39 (q,  $J=7.2$  Hz, 2H) 1.96-2.10 (m, 1H) 1.77-1.91 (m, 1H) 1.19-1.61 (m, 5H) 0.98 (t,  $J=7.3$  Hz, 3H); MS (M+1): 469.3.

#### Biological Data

##### Glucagon cAMP Assay

The Cisbio cAMP detection assay is used to determine the ability of putative glucagon antagonist to block glucagon induced cAMP production. Potential glucagon antagonists are re-suspended and diluted in 100% DMSO. Prior to use in the Glucagon cAMP assay 100x DMSO compound stocks are diluted 20x with DMEM-F12 media (Invitrogen) containing either 0.1% or 4% BSA. 2 μL of 5x compound stocks are spotted into the appropriate wells of low binding white solid bottom 384 well plates (Corning). 2 μL of 5% DMSO or known glucagon antagonist are added to each plate to define the assay window. CHOK1 cells stably transfected with the human glucagon receptor are removed from culture flasks with cell dissociation buffer. Cell pellets are re-suspended, at a concentration of 8.3e<sup>5</sup> cells/mL in DMEM-F12 with or without 4% BSA and 200 μM IBMX. 6 μL of cell suspensions are added to the assay plates. Plates are incubated for 20 min at room temperature prior to the addition of a 100 pM challenge dose of glucagon. On a separate plate glucagon dose response curves are run to determine the EC<sub>50</sub> of glucagon. After a 30 min room temperature incubation the reaction is terminated by the addition of lysis buffer containing the cAMP detection reagents. Plates are incubated for an additional 60 min at room temperature prior to being read on the Perkin Elmer

## Human Glucagon SPA Assay

The Glucagon SPA assay is used to determine the ability of test compounds to block the binding of glucagon-cex to the glucagon receptor. Test compounds are re-suspended and serially diluted in 100% DMSO. 1  $\mu$ l of test compound at the desired concentrations is spotted into the appropriate wells of 96 well low binding white clear bottom plate (Corning). 1  $\mu$ l of DMSO is spotted into total binding wells. 1  $\mu$ l of a known glucagon antagonist at a concentration of 20  $\mu$ M is added to non specific binding wells. 0.3-0.75  $\mu$ g of membrane from chem-1 cells stably transfected with the human glucagon receptor (Millipore), 125 pM of [ $^{125}$ I]Glucagon-Cex (Perkin Elmer) and 175  $\mu$ g of WGA PVT SPA beads (Perkin Elmer) are added to all wells of the assay plate. All assay ingredients with the exception of test compounds are re-suspended in the following buffer; 50 mM Hepes pH 7.4; 5 mM  $MgCl_2$ ; 1 mM  $CaCl_2$ ; 5% glycerol and 0.2% BSA. Following a 6-10 hr incubation at room temperature the amount of hot ligand bound to the cell membranes is

Data is analyzed using Pfizer's Data analysis program.  $IC_{50}$  values are then determined from the generated sigmoidal dose response curves.  $K_i$  values are calculated using Cheng-Prusoff equation. N is the number of times the compound was assayed.
